

One leg is priced. The other is not

Swiss customs gold trade with the United States against the New York premium. Each dot is one month, January 2023 to November 2025

Estimated on the tariff window alone: 2020 and the 2022 sanctions shock are location dislocations of a different kind, and folding them in widens the claim past what this paper argues. It costs precision, not the result - the full 2015-2026 series puts the threshold at \$2.99 against \$3.02 here. Method: a continuous kink, tonnes = $a + b_1(x-g) + b_2 \max(0, x-g)$, with g by profile least squares, 15% trimmed from each regime, and a 90% interval from 2,000 iid and moving-block bootstrap replications. On 35 months that interval is wide - \$0.77 to \$10.82 - and dropping the three largest months moves the point estimate to \$4.72. The threshold is well located and poorly pinned. Westward: R-squared 0.44 against 0.36 for a straight line, slope below the threshold 0.5 tonnes per dollar. Eastward: straight-line R-squared 0.000 and a correlation of +0.02, so no line is fitted.
