

The price of being on the right side of the border

COMEX gold futures over London spot, 90-day constant maturity, in excess of financing and storage. Arbitrage should hold this at zero

Constant maturity, not the front month: the raw spread carries the roll sawtooth, and the front-month annualised rate divides by days to delivery, which sends it to 42% a fortnight before notice. Both are calendar artefacts. Daily dots are clipped to the frame: 41 of 389 sessions fall outside it. The New York settlement is struck three hours after the London fix, so a 1% move in between is worth four points annualised - which is why the daily figure is plotted as scattered points and read through a ten-session mean. Note also that the premium fell hard at the exemption but never returned to the pre-election band - it settled near half a point for the rest of 2025.
